AB   A multivalently interactive mol. assembly having a plurality of functional
     groups or ligands, in which a ratio between Rh and Rg expressed as Rh/Rg
     is 1.0 or less.  Here, Rh is a hydrodynamic radius calculated from dynamic
     light scattering (DLS) assay performed in aqueous solution; and Rg is a radius
of
     gyration determined based on the Zimm plot generated using data obtained by
     static light scattering (SLS) assay.  A polyrotaxane was prepared from
     α-cyclodextrin and diamino-PEG and reacted with Z-L-Phe succinimide
     ester.  Then biotin mols. were introduced into the polyrotaxane mol.
     Examples were given of anal. of biotin-polyrotaxane conjugate binding to
     streptavidin-immobilized surface using surface plasmon resonance.  Trypsin
     activity inhibition and Ca chelating activities of polyrotaxanes were also
     given.

AB It is intended to provide a tissue-specific transporter inhibitor which is not absorbed in the digestive tract and can prevent worsening in the quality of life (QOL) of a patient due to diet therapy; and remedies for tissue dysfunction diseases and remedies for chronic renal failure progress containing the above inhibitor as the active ingredient. The tissue-specific transporter inhibitor not absorbed in the digestive tract is prepared by introducing a dipeptide which is a ligand of oligopeptide transporter 1 into a supermol. structure polyrotaxane which is expected as being excellent in the interaction of its structurally modified active residue with a transmembrane transporter.

AB The invention relates to a multivalently interactive mol. assembly which can effectively and stably bind to a target substance in vivo or in vitro, a capturing agent comprising said multivalently interactive mol. assembly for capturing an object of interest in vivo or in vitro, a drug carrier which aids administration of a drug, a calcium chelating agent which can effectively chelate calcium, and a drug enhancer which can be administered with a drug to assist in e.g. absorption of the drug. The invention discloses a multivalently interactive mol. assembly having a plurality of functional groups or ligands, in which a ratio between Rh and Rg expressed as Rh/Rg is 1.0 or less. Here, Rh is a hydrodynamic radius calculated from a

dynamic light scattering assay performed in aqueous solution, and Rg is a radius of gyration determined based on the Zimm plot generated using data obtained by a static light scattering assay. Specifically, the invention discloses polyrotaxanes, the synthesis of which is described.

AB A review. The challenge to multivalent binding between ligands and proteins or biol. receptors on cell surfaces has been focused on using supramol.-structured polymers, polyrotaxanes. Our designed polyrotaxanes consist of ligand-immobilized α-cyclodextrins (α-CDs) threaded onto a linear polymeric chain (polyethylene glycol) (PEG) capped both terminals with bulky end-groups via biodegradable linkages. Structural characteristics of these polyrotaxanes involve sliding and rotational motion of the ligands immobilized on α-CDs along a PEG chain as to easily face to binding sites on proteins, which can contribute much to enhanced multivalent binding with proteins.

LANGUAGE: English

AB A review. The synthesis, properties, and potential applications of rotaxane dendrimers, dendritic mols. containing rotaxane -like mech. bonds to link their components are described. Rotaxane dendrimers are classified into three types depending on where rotaxane-like features are introduced - Type I, II, and III rotaxane dendrimers which incorporate rotaxane -like features at the core, termini, and branches, resp. Several different types of macrocycles are employed as the ring component in the templated synthesis of rotaxane dendrimers. In the synthesis of rotaxane dendrimers, several aspects should be carefully considered, including the binding affinity of the macrocycle (ring) and guest (rod). The properties of these rotaxane dendrimers are quite different from those of the individual rotaxanes or dendrimers and often a blend of both. Potential applications of rotaxane dendrimers include mol. nanoreactors, drug delivery, and gene delivery.

ENTRY DATE: Entered STN: 27 Mar 2003
Last Updated on STN: 27 Mar 2003

AB This article reviews controlled release from crosslinked degradable networks. Network formulations include those derived from wholly synthetic components, natural components, and combinations thereof. This includes, but is not limited to, poly(orthoesters), poly(anhydrides), poly(ethylene glycol) (PEG) derivatives, and dextran functional macromonomers. In addition, we present a discussion of the chemistry behind novel degradable networks with potential use in the controlled release realm.

DOCUMENT TYPE: Journal
LANGUAGE: English
AB Kinetic anal. of interactions between biotin-polyrotaxane or biotin-α-cyclodextrin (biotin-α-CD) conjugates and streptavidin was carried out as a model of new targeting to transporters using the surface plasmon resonance (SPR) technique. The biotin-polyrotaxane conjugates, in which biotin-introduced α-CDs are threaded onto a poly(ethylene oxide) chain capped with bulky end-groups, are expected to increase the valency of biotin from monovalent to multivalent binding. The number of biotins conjugated with one polyrotaxane mol. varied from 11 to 78, and apparently increased the association equilibrium constant (Ka), assuming pseudo-first-order kinetics. A detailed dissociation kinetics was analyzed and the re-binding of the biotin-polyrotaxane conjugates was observed on the streptavidin-deposited SPR surface. The magnitude of the re-binding is likely to become larger with increasing the number of biotins, suggesting multivalent interaction on the SPR surface. To quantify the effect of valency, competitive inhibition assay was performed in terms of the supramol. structure of the polyrotaxane. The inhibitory potency of the biotin-polyrotaxane conjugate was found to be 4-5 times greater than that of the biotin-α-CD conjugate. Therefore, the biotin-polyrotaxane conjugates by supramol. formation of the biotin-α-CD conjugate significantly switches from monovalent to multivalent bindings to the model binding protein, streptavidin.

LANGUAGE: English
AB A carboxyethylester-polyrotaxane was synthesized as a novel calcium chelating polymer in the field of oral drug delivery and characterized in terms of mechanism of trypsin inhibition. Here, carboxyethyl ester (CEE) groups are introduced to all the primary hydroxyl groups in α-cyclodextrins (α-CDs), which are threaded onto a poly(ethylene glycol) chain capped with bulky end-groups (polyrotaxane). The solubility of the CEE-polyrotaxane in physiol. conditions increased with pH, indicating ionization-related solubility similar to conventional polyacrylates. The ability of calcium (Ca2+) chelation was found to increase in the order of poly(acrylic acid) (PAA)>CEE-polyrotaxane»CEE-α-CD, suggesting that the increased d. of carboxyl groups enhances the Ca2+ chelating ability. The activity of trypsin was inhibited by these compds. in the same order of the calcium chelation. However, the inhibitory effect of CEE-polyrotaxane was reduced by adding excess Ca2+ without precipitation that was observed in the presence of PAA.
Such the reduced inhibition and precipitation by CEE-α-CD was not observed Therefore, the inhibitory effect of CEE-polyrotaxane is due to Ca2+ chelation from trypsin without non-specific interaction.

AB A polyrotaxane-biotin conjugate was synthesized and its interaction with streptavidin measured using surface plasmon resonance (SPR) detection. A biodegradable polyrotaxane in which .apprx.22 mols. of α-cyclodextrins (α-CDs) were threaded onto a poly(ethylene oxide) chain (Mn: 4,000) capped with benzyloxycarbonyl-L-phenylalanine was conjugated with a biotin hydrazide and 2-aminoethanol after activating the hydroxyl groups of α-CDs in the polyrotaxane using N,N'-carbonyldiimidazole. The results of the high-resolution 1H-NMR (1H-NMR) spectra and gel permeation chromatog. of the conjugate showed that .apprx.11 biotin mols. were actually introduced to the polyrotaxane scaffold. An SPR anal. showed that the binding curves of the biotin mols. in the conjugate on the streptavidin-deposited surface changed in a concentration dependent manner, indicating that the biotin in the conjugate was actually recognized by streptavidin. The association equilibrium constant (Ka) of the interaction between the conjugate and streptavidin tetramer was of the order 107. These results suggest that polyrotaxane is useful for scaffolds as a polymeric ligand in biomedical fields.

AB A polyrotaxane consisting of α-cyclodextrins (α-CDs) and α,ω-di(glycylglycyne) polyoxyethylene (α,ω-di(Gly-Gly)-PEG) capped with tyrosine was synthesized as a drug carrier and its in vitro degradation by aminopeptidase M was demonstrated. α,ω-Di(Gly-Gly)-PEG was prepared by condensation reaction between terminal amino-groups in α-(3-aminopropyl)-ω-(3-aminopropyl) polyoxyethylene and succinimide ester of N-tert-butyloxycarbonyl (Boc)-Gly-Gly, followed by the deprotection of Boc group via acidic hydrolysis. A polypseudorotaxane consisting of α-CDs and

α,ω-di(Gly-Gly)-PEG was prepared in the mixture of water and dimethylsulfoxide. The polyrotaxane was successfully synthesized by condensation reaction between the amino-groups in the pseudopolyrotaxane and p-nitrophenyl ester of carbobenzoxy L-tyrosine. The addition of 1-hydroxy-1H-benzotriazole on the reaction was found to increase the yield and the number of α-CDs in the polyrotaxane. Hydroxypropylation of the polyrotaxane improved the solubility in aqueous solns. and many kinds of organic solvents. In vitro degradation of the hydroxypropylated (HP-)polyrotaxane revealed that HP-α-CDs in the HP-polyrotaxane were released in the presence of aminopeptidase M. These results suggest that the supramol. dissociation will be triggered by the action of extra-cellular enzymes and lead to a new mechanism of drug release from polymeric drug carriers.

AB This article reviews with 91 refs. the potential of polyrotaxanes in drug delivery with the historical background of polyrotaxane syntheses. Pseudopolyrotaxanes and polyrotaxanes, including classifications, synthetic methods, structures and phys. properties are discussed in the first section. The second section provides our concept of drug carriers using drug-polyrotaxane conjugates in comparison with conventional drug-polymer conjugates. The third and fourth sections describe the synthetic method for biodegradable polyrotaxanes, the conjugation with drugs, and their association under physiol. conditions. The fifth section discusses other possibilities for the polyrotaxanes such as drug penetration enhancers. These studies suggest the potential of polyrotaxanes in pharmaceutical applications.

AB For efficient application as drugs, potent oligopeptides must overcome a number of phys. and enzymic barriers presented. Amongst these are the susceptibility of peptides to the action of hydrolytic enzymes and their poor membrane transport properties. Temporary encapsulation of peptides by a macrocycle in the form of [2]rotaxanes is proposed as a possible solution to these problems. For application as a drug delivery systems one of the stoppers attached to the end of oligopeptide thread should be degradable under physiol. conditions allowing the 'slippage' of the macrocycle. We investigated the application of oligosaccharides as biodegradable stoppers for [2] rotaxanes based on GlyGly. [2]Rotaxanes 1 and 2a were prepared through the 'clipping' strategy. After deprotection of the sugar portions of these compds. only rotaxane 2b was stable. The disassembling of 2b can be achieved through the action of a-mannosidases.

AB Supramol. dissociation of biodegradable polyrotaxanes via terminal hydrolysis by an enzyme (papain) in vitro was investigated in relation to their solution properties. The polyrotaxanes were synthesized by the introduction of L-phenylalanine (L-Phe) at both ends of an inclusion complex consisting of α-cyclodextrins (α-CDs) and amino-terminated poly(ethylene glycol) (PEG) via peptide linkages, followed by the hydroxypropylation of α-CDs. From static and dynamic light scattering studies, it was clarified that the polyrotaxanes form a loosely packed association but L-Phe-terminated PEGs form a tightly packed association Further, the polyrotaxanes were found to maintain their rod-like structures in physiol. conditions. In vitro degradation expts. using papain revealed that the terminal hydrolysis of the polyrotaxanes is completed and accompanied by the release of hydroxypropylated α-CDs, and this behavior is not affected by the association number of the polyrotaxanes. On the other hand, the terminal hydrolysis of L-Phe-terminated PEG is limited under similar conditions. From these results, the complete dissociation of the polyrotaxanes by hydrolysis is considered to be due to the loosely packed association, presumably related to the rod-like structure. The potential for drug delivery is discussed.

AB The topical preparation contains indomethacin (I) and a biodegradable polymer assembly having a supramol. structure which comprises a number of α-, β-, or γ-cyclodextrin, a linear polymer penetrating through the hollows of the cyclodextrins, and biodegradable moieties bonded to both ends of the polymer. The unique polymer assembly improves transdermal absorption of drugs without causing skin irritation and toxicity. A saturated α-cyclodextrin solution was treated with PEG 4000BA [α-(3-aminopropyl)-ω-(3-aminopropoxy)poly(oxyethylene)] and the resulting turbid solution was ultrasonicated then let stand overnight to give a pseudopolyrotaxane comprising 35-40 cyclodextrin mols. and a threading polyoxyethylene chain. The pseudopolyrotaxane was treated with a DMS solution of Z-L-Phe-Su, prepared from carbobenzoxy-L-phenylalanine and N-hydroxysuccinimide, to give Z-L-Phe-polyrotaxane. This was hydroxypropylated with propylene oxide, followed by deprotection of carbobenzoxy group. Permeation of I through a sheet of hairless mouse skin pretreated with the hydroxypropylated polyrotaxane was 19.27 μg/cm3 for 8 h, vs. 9.10 μg/cm3 for a control using H2O as pretreatment agent.

AB Polyrotaxanes were synthesized as novel biodegradable polymers with supramol. assembly and their properties evaluated in vitro. The synthesis of biodegradable polyrotaxanes consists of three steps: preparation of an inclusion complex consisting of α-cyclodextrins (α-CDs) and amino-terminated poly(ethylene glycol) (PEG); introduction of L-phenylalanine (L-Phe) at each complex terminal via peptide linkages; and hydroxypropylation of α-CDs in the polyrotaxanes. Succinimide ester of benzyloxycarbonyl-L-Phe was condensed with the terminal amino groups of the inclusion complex. 1H-NMR and GPC results showed that α-CDs were threaded onto a PEG chain and L-Phe moieties were introduced at each terminal of the PEG chain. Further, the amount of threaded α-CDs was found to be governed by the mol. weight of PEG. The hydroxypropylation of α-CDs improved the solubility of the polyrotaxanes in PBS (pH 7.4). The hydroxypropylated (HP-) polyrotaxanes were characterized by terminal peptide cleavage using papain. In vitro degradation of HP-polyrotaxanes revealed that HP-α-CDs threaded onto a PEG chain were released only when terminal peptide linkages were cleaved. Moreover, threaded HP-α-CDs chain were released only when terminal peptide linkages were cleaved. Moreover, threaded HP-α-CDs onto a PEG chain was found to be completely released. Kinetics of terminal peptide cleavage were also evaluated by catalytic efficiency (kcat/Km). The kcat/Km values were found to be independent of the mol. weight of HP-polyrotaxanes but to be affected by terminal hydrophobic moieties. It is proposed that our designed polyrotaxanes are feasible as novel drug carriers.

AB Polyrotaxanes are well known as a supramol. assembly in which many cyclic compds. are threaded onto a linear polymeric chain capped with bulky end-groups. In this paper, a polyrotaxane consisting of α-CDs and PEG capped with biodegradable peptide moieties was synthesized, and the interaction with stratum corneum of hairless rat skin was examined by means of a differential scanning calorimetry. The hydroxypropylated polyrotaxane was found to interact with lipid components in the stratum corneum: bound water content was significantly decreased although ordered lipid bilayers were maintained. Thus, it is suggested that our designed polyrotaxane can be feasible as novel candidates for transdermal penetration enhancers.

AB The invention relates to a highly water-soluble polymer having arbitrarily controllable drug-carrying capacity and drug-releasing characteristics and serving as a novel drug carrier widely applicable in vivo; and a biodegradable medicinal polymer assembly having a supermol. structure and being capable of releasing a drug in response to a specific biodegrdn.

occurring in each disease. The assembly comprises a number of drug-carrying cyclic compds. prepared by binding a drug to α, β or γ-cyclodextrin, a linear polymer penetrating through the hollows of the cyclic compds., and biodegradable moieties bonded to both ends of the polymer. A biodegradable medicinal polymer assembly with supermol. structure for mitomycin C delivery is given as an example.

AB Biodegradable polymers with supramol. structures were proposed as a novel candidate of substrates for temporal drug delivery. A biodegradable polyrotaxane was synthesized in which α-cyclodextrins (α-CDs) as drug carriers were threaded onto a poly(ethylene glycol) (PEG) chain capped at each terminal with L-phenylalanine (L-Phe) via peptide linkages. The release of α-CDs from the biodegradable polyrotaxane was observed only when the terminal peptide linkages were hydrolyzed by papain. Further, the dethreading process of α-CDs from PEG chains was also observed to be quite rapid. Therefore, it is suggested that α-CD release from the biodegradable polyrotaxane was controlled by the hydrolysis of terminal peptide linkages.

AB   A multivalently interactive mol. assembly having a plurality of functional
     groups or ligands, in which a ratio between Rh and Rg expressed as Rh/Rg
     is 1.0 or less.  Here, Rh is a hydrodynamic radius calculated from dynamic
     light scattering (DLS) assay performed in aqueous solution; and Rg is a radius
of
     gyration determined based on the Zimm plot generated using data obtained by
     static light scattering (SLS) assay.  A polyrotaxane was prepared from
     α-cyclodextrin and diamino-PEG and reacted with Z-L-Phe succinimide
     ester.  Then biotin mols. were introduced into the polyrotaxane mol.
```

Examples were given of anal. of biotin-polyrotaxane conjugate binding to streptavidin-immobilized surface using surface plasmon resonance. Trypsin activity inhibition and Ca chelating activities of polyrotaxanes were also given.

AB A review. The synthesis, properties, and potential applications of rotaxane dendrimers, dendritic mols. containing rotaxane-like mech. bonds to link their components are described. Rotaxane dendrimers are classified into three types depending on where rotaxane-like features are introduced - Type I, II, and III rotaxane dendrimers which incorporate rotaxane-like features at the core, termini, and branches, resp. Several different types of macrocycles are employed as the ring component in the templated synthesis of rotaxane dendrimers. In the synthesis of rotaxane dendrimers, several aspects should be carefully considered, including the binding affinity of the macrocycle (ring) and guest (rod). The properties of these rotaxane dendrimers are quite different from those of the individual rotaxanes or dendrimers and often a blend of both. Potential applications of rotaxane dendrimers include mol. nanoreactors, drug delivery, and gene delivery.

AB A polyrotaxane consisting of α-cyclodextrins (α-CDs) and α,ω-di(glycylglycyne) polyoxyethylene (α,ω-di(Gly-Gly)-PEG) capped with tyrosine was synthesized as a drug carrier and its

in vitro degradation by aminopeptidase M was demonstrated. α,ω-Di(Gly-Gly)-PEG was prepared by condensation reaction between terminal amino-groups in α-(3-aminopropyl)-ω-(3-aminopropyl) polyoxyethylene and succinimide ester of N-tert-butyloxycarbonyl (Boc)-Gly-Gly, followed by the deprotection of Boc group via acidic hydrolysis. A polypseudorotaxane consisting of α-CDs and α,ω-di(Gly-Gly)-PEG was prepared in the mixture of water and dimethylsulfoxide. The polyrotaxane was successfully synthesized by condensation reaction between the amino-groups in the pseudopolyrotaxane and p-nitrophenyl ester of carbobenzoxy L-tyrosine. The addition of 1-hydroxy-1H-benzotriazole on the reaction was found to increase the yield and the number of α-CDs in the polyrotaxane. Hydroxypropylation of the polyrotaxane improved the solubility in aqueous solns. and many kinds of organic solvents. In vitro degradation of the hydroxypropylated (HP-)polyrotaxane revealed that HP-α-CDs in the HP-polyrotaxane were released in the presence of aminopeptidase M. These results suggest that the supramol. dissociation will be triggered by the action of extra-cellular enzymes and lead to a new mechanism of drug release from polymeric drug carriers.

AB A review, with 25 refs. Polyrotaxanes as a supramol.-structured polymer were characterized aiming at a drug carrier, a drug permeation enhancer, an implantable material, and a stimuli-responsive material. Biodegradable polyrotaxanes exhibit their supramol. architectures: many α-cyclodextrins (α-CDs) are threaded onto a single poly(ethylene glycol) (PEG) chain capped with biodegradable bulky end-groups. Further, a stimuli-responsive polyrotaxane, in which many β-CDs are threaded onto a triblock-copolymer of PEG and poly(propylene glycol) (PPG) capped with fluorescein-4-isothiocyanate, was designed as a novel smart material.

AB The discovery of a simple hydrogen bonding template for rotaxane formation has led to investigations into the potential of using rotaxanes of biol. active peptides as novel drug delivery systems. Here we describe how rotaxane formation imparts enzyme stability upon the peptide and how manipulation of the solubility and transport properties can be achieved through functionalisation of the rotaxane macrocycle.

AB A review with 51 refs. This article reviews our concept of drug delivery systems using drug/polyrotaxane conjugates as drug carriers. The biodegradable polyrotaxanes exhibit their supramol. architectures: many α-cyclodextrins are threaded onto a single poly(ethylene glycol) chain capped with biodegradable bulky end-groups. The synthetic method of the polyrotaxanes, the conjugation with drugs, and their association nature in a physiol. condition are described. The supramol. dissociation of the drug/polyrotaxane conjugates via terminal peptide cleavage by a hydrolytic enzyme is discussed in relation to their association nature. Through these studies, advantages of drug/polyrotaxane conjugates as drug carriers are suggested in comparison with conventional drug/polymer conjugates.

AB For efficient application as drugs, potent oligopeptides must overcome a number of phys. and enzymic barriers presented. Amongst these are the susceptibility of peptides to the action of hydrolytic enzymes and their poor membrane transport properties. Temporary encapsulation of peptides by a macrocycle in the form of [2]rotaxanes is proposed as a possible solution to these problems. For application as a drug delivery systems one of the stoppers attached to the end of oligopeptide thread should be degradable under physiol. conditions allowing the 'slippage' of the macrocycle. We investigated the application of oligosaccharides as biodegradable stoppers for [2]rotaxanes based on GlyGly. [2]Rotaxanes 1 and 2a were prepared through the 'clipping' strategy. After deprotection of the sugar portions of these compds. only rotaxane 2b was stable. The

disassembling of 2b can be achieved through the action of a-mannosidases.

AB This article reviews with 91 refs. the potential of polyrotaxanes in drug delivery with the historical background of polyrotaxane syntheses. Pseudopolyrotaxanes and polyrotaxanes, including classifications, synthetic methods, structures and phys. properties are discussed in the first section. The second section provides our concept of drug carriers using drug-polyrotaxane conjugates in comparison with conventional drug-polymer conjugates. The third and fourth sections describe the synthetic method for biodegradable polyrotaxanes, the conjugation with drugs, and their association under physiol. conditions. The fifth section discusses other possibilities for the polyrotaxanes such as drug penetration enhancers. These studies suggest the potential of polyrotaxanes in pharmaceutical applications.

AB Theophylline-polyrotaxane conjugates were synthesized by coupling theophylline with α-cyclodextrins (α-CDs) in the polyrotaxane. The polyrotaxane is a mol. assembly in which many α-CDs are threaded onto a poly(ethylene glycol) (PEG) chain capped with L-phenylalanine (L-Phe). Theophylline-7-acetic acid was activated by coupling with 4-nitrophenol, and then ethylenediamine was allowed to react with the active ester in order to obtain N-aminoethyltheophylline-7-acetoamide. This derivative was coupled with a 4-nitrophenyl chloroformate-activated polyrotaxane to obtain the theophylline-polyrotaxane conjugates. The conjugates formed a specific association under physiol. conditions, depending upon interactions between the theophylline mols. and/or the terminal L-Phe moiety in the conjugates. In vitro degradation of the conjugates revealed that theophylline-immobilized α-CDs were completely released by hydrolysis of the terminal peptide linkage in the polyrotaxane. This result indicates that the association of the conjugates does not induce the steric hindrance but rather enhances the accessibility of enzymes to the

terminal peptide linkages. It is suggested that our designed drug-polyrotaxane conjugates can release the drugs via the dissociation of the supramol. structure without steric hindrance of enzymic accessibility to the terminal peptide linkages.

AB The invention concerns a method for obtaining a fluorescent conjugate between a binding mol. having at least an amino, hydroxy, carboxy and/or sulfydryl group and a fluorophore reagent having at least a functional group capable of reacting with said amino, hydroxy, carboxy and/or sulfydryl group(s), in the presence of an aqueous solution of a water-soluble macrocycle. The binding mol. conjugates to the fluorophore and in the presence of the macrocycle a stable rotaxane-like inclusion complex is formed; thus the aggregation of the fluorescent conjugates is prevented. The macrocycle is a cyclodextrin, a cyclodextrin derivative, or a calixarene. Reactive fluorophores are e.g. cyanine dyes, fluorescein etc. The binding mols. can be antibodies, antigens, proteins, avidin, haptens, toxins, hormones , drugs, polymers, glass, polysaccharides, nucleic acids etc. The invention also concerns the conjugates obtained by this method and their use.

AB Polyrotaxanes were synthesized as novel biodegradable polymers with supramol. assembly and their properties evaluated in vitro. The synthesis of biodegradable polyrotaxanes consists of three steps: preparation of an inclusion complex consisting of α-cyclodextrins (α-CDs) and amino-terminated poly(ethylene glycol) (PEG); introduction of L-phenylalanine (L-Phe) at each complex terminal via peptide linkages; and hydroxypropylation of α-CDs in the polyrotaxanes. Succinimide ester of benzyloxycarbonyl-L-Phe was condensed with the terminal amino groups of the inclusion complex. 1H-NMR and GPC results showed that α-CDs were threaded onto a PEG chain and L-Phe moieties were introduced at each terminal of the PEG chain. Further, the amount of threaded α-CDs was found to be governed by the mol. weight of PEG. The hydroxypropylation of α-CDs improved the solubility of the polyrotaxanes in PBS (pH 7.4). The hydroxypropylated (HP-) polyrotaxanes were characterized by terminal peptide cleavage using papain. In vitro degradation of HP-polyrotaxanes revealed that HP-α-CDs threaded onto a PEG chain were released only when terminal peptide linkages were cleaved. Moreover, threaded

HP-α-CDs chain were released only when terminal peptide linkages were cleaved. Moreover, threaded HP-α-CDs onto a PEG chain was found to be completely released. Kinetics of terminal peptide cleavage were also evaluated by catalytic efficiency (kcat/Km). The kcat/Km values were found to be independent of the mol. weight of HP-polyrotaxanes but to be affected by terminal hydrophobic moieties. It is proposed that our designed polyrotaxanes are feasible as novel drug carriers.

AB Biodegradable polymers with supramol. structures were proposed as a novel candidate of substrates for temporal drug delivery. A biodegradable polyrotaxane was synthesized in which α-cyclodextrins (α-CDs) as drug carriers were threaded onto a poly(ethylene glycol) (PEG) chain capped at each terminal with L-phenylalanine (L-Phe) via peptide linkages. The release of α-CDs from the biodegradable polyrotaxane was observed only when the terminal peptide linkages were hydrolyzed by papain. Further, the dethreading process of α-CDs from PEG chains was also observed to be quite rapid. Therefore, it is suggested that α-CD release from the biodegradable polyrotaxane was controlled by the hydrolysis of terminal peptide linkages.

AB The invention relates to a highly water-soluble polymer having arbitrarily controllable drug-carrying capacity and drug-releasing characteristics and serving as a novel drug carrier widely applicable in vivo; and a biodegradable medicinal polymer assembly having a supermol. structure and being capable of releasing a drug in response to a specific biodegrdn. occurring in each disease. The assembly comprises a number of drug-carrying cyclic compds. prepared by binding a drug to α, β or γ-cyclodextrin, a linear polymer penetrating through the hollows of the cyclic compds., and biodegradable moieties bonded to both ends of the polymer. A biodegradable medicinal polymer assembly with supermol. structure for mitomycin C delivery is given as an example.

AB The binding domain of an antibody is a paradigm for the development of a synthetic host. Host-rotaxanes combine recognition elements in a similar convergent arrangement as found with antibodies. Besides forming tight complexes with various guests, host-rotaxanes are highly efficient cellular transport agents. The rotaxane operates through a passive transport mechanism, so there is no control over what cell it enters. We are currently constructing host-rotaxanes with an "on" switch to obtain cell-selectivity. Highly charged peptides will be added to the transporters, which should make them impermeable. Enzymic cleavage of these peptides will turn the transporter on and it will enter cells. The long-term goal is to create transporters that are turned on by enzymes that are over expressed at tumor sites. These transporters will become part of a new anti-cancer therapy.

AB A review. Mesoporous silica thin films and nanoparticles prepared by surfactant-templated sol-gel techniques are versatile substrates that can be easily derivatized with active mols. to create functional materials. By exploiting the chemical and phys. differences that exist in different regions of the mesostructure, active mols. can be deliberately placed using one-pot techniques, or they can be tethered to the exposed surfaces post-synthetically. The methods available for functionalization have been used to design operational machines including nanoimpellers based on the dynamic photoisomerization of azobenzene, and nanovalves based on the switchable motion of supramol. rotaxanes and pseudorotaxanes. The ability of nanoimpellers and nanovalves to control the release of mols. from the pores of mesoporous silica materials is demonstrated using luminescence spectroscopy. These machines can be designed to operate under a range of external stimuli, including light, elec. (redox) or chemical (pH, competitive binding) energy, making them useful systems for a variety of controlled release applications. Mesoporous silica nanoparticles not functionalized with mol. machines are capable of delivering water-insol. anticancer drugs to cancer cells. Carefully designed nanoimpellers and nanovalves supported on mesoporous silica nanoparticles offer the ability to develop sophisticated drug delivery vehicles for a wide range of drug mols.

AB In the development of anti-cancer drugs, it is important to yield selective cytotoxicity primarily against tumor tissues. To achieve this goal, the use of a polymer-drug conjugate appears to be appealing, simply because it can take the advantage of the so-called enhanced permeability and retention (EPR) effect due to vascular leak in tumors. Among various types of polymers, polyrotaxane (PR) is an interesting candidate and warrants further consideration. It is a self-assembled polymer made entirely of biocompatible components, by threading α-cyclodextrin (α-CD) mols. with the poly(ethylene glycol) (PEG) chain. The abundance in functional -OH groups on the CD residues renders PR the capability of carrying a large dose of small anti-tumor agents for delivery. Herein, we presented a novel PR-based delivery system using doxorubicin (DOX) as the model anti-cancer drug. Daunorubicin (DNR) was conjugated to the PR polymer via hydrolysable linkages, and upon hydrolysis, doxorubicin was released as the cytotoxic drug. To facilitate an intracellular uptake by the tumor cells of the PR-DOX conjugates, a cell-penetrating low mol. weight protamine (LMWP) peptide was further attached to the two termini of the PR chain. Using an innovative principle established in our laboratory, such as via the inhibition of the cell-penetrating activity by binding with heparin and reversal of this inhibition by subsequent addition of protamine, cellular uptake of the polymer-drug conjugates could be readily regulated.

In this paper, we performed in vitro studies to demonstrate the feasibility of this delivery system. The LMWP-PR-DOX conjugates, which yielded a sustained release of DOX over a period of greater than 4 days, were successfully synthesized. Intracellular uptake of these conjugates by A2780 human ovarian cancer cells and regulation of such uptake by heparin and protamine were confirmed by using the MTT assay and also the confocal microscopy method.

AB Supramol. chemical has been employed to develop flexible and adaptable multivalent neoglycoconjugates for binding galectin-1 (Gal-1). Gal-1, a dimeric lectin with two galactoside-binding sites, regulates cancer progression and immune responses. Self-assembled pseudopolyrotaxanes consisting of lactoside-displaying cyclodextrin (LCD) "beads" threaded onto polyviologen "strings" display mobile ligands as a result of cyclodextrin rotation about, and limited translation along, the polymer chain. The pseudopolyrotaxanes rapidly and efficiently precipitate Gal-1 and provide valency-corrected enhancements of up to 30-fold compared to native lactose and 20-fold over free LCD in a T-cell agglutination assay. A supramol. statistical effect was observed, wherein the efficacy of Gal-1 inhibition correlates with the number of ligands connected to each other solely through mech. and noncovalent interactions. Such flexible and adaptable self-assembled pseudopolyrotaxanes show promise for the study of multivalent interactions and targeting of therapeutically relevant lectins.

AB This review describes the development of self-assembled multivalent pseudopolyrotaxanes as flexible and dynamic neoglycoconjugates for binding Galectin-1 (Gal-1). Gal-1, a dimeric lectin with two lactoside-binding sites, plays multiple roles in a variety of cancers. Pseudopolyrotaxanes comprised of lactoside-displaying cyclodextrin (LCD) "beads" threaded onto polyviologen "strings" display highly flexible and adaptable ligands as a result of rotation of the cyclodextrin torus about, and limited translation along, the polymer chain. The pseudopolyrotaxanes rapidly and efficiently precipitate Gal-1 and provide valency-corrected enhancements of up to 30-fold over native lactose and 20-fold over free LCD in a T-cell agglutination assay. These results show that the flexible and dynamic ligand presentation afforded by supramol. assemblies, such as the pseudopolyrotaxanes, is a useful strategy for the study of protein-carbohydrate interactions and the exploitation of multivalency for targeting therapeutically relevant lectins.

AB The present invention provides for methods and compns. for transporting agents and macromols. across biol. membranes. In one embodiment, the invention relates to a method for enhancing transport of a selected agent across a biol. membrane, wherein a biol. membrane is contacted with a composition containing a biol. active rotaxane capable of selectively transporting the selected agent. The host-rotaxane is effective to impart to the agent an amount of transport and/or rate of trans-membrane transport across a biol. membrane that is greater than the amount and/or rate of trans-membrane transport of the agent without the host-rotaxane.

AB Polyrotaxanes which comprise 2-50 cyclic oligosaccharides threaded onto a linear polyoxyalkylene terminated with substituents ≥0.6 nm in diameter, with metal complexes or triiodobenzoyl moieties as substituents on the cyclic oligosaccharides, are useful as contrast agents for MR tomog. and x-ray diagnosis. These compds., with a mol. weight of 104-2 + 105, accumulate in regions of elevated vascular permeability (e.g. tumors), give information on perfusion of tissues and on blood volume, and are useful in angiog., lymphog., and diagnosis of inflammation. These polyrotaxanes, when used in MR imaging and diagnosis, can be 10-20% saturated with paramagnetic cations, compared to 5% for dextran chelate derivs. used previously. They can be administered parenterally in doses <1 mg/kg as solns. isoosmolar to blood, are relatively nontoxic, and are completely eliminated from the body. They are prepared by reaction of cyclic oligosaccharides with H-terminated polyoxyalkylenes in a polar solvent, followed by functionalized terminating groups.

AB Camptothecin (CPT) is a naturally occurring alkaloid that shows promise in antitumor activity in vitro against various tumor cell lines. Its potential clinical uses, however, are hindered by a lack of reaction selectivity and poor water solubility. Presented herein is a novel polyrotaxane (PR)-based delivery system that could potentially lead to a highly effective yet less toxic CPT therapy. The approach involves the synthesis of the PR-CPT conjugates via hydrolyzable linkages. To enhance the therapeutic efficacy of CPT, a cell-penetrating peptide, LMWP, is linked to the conjugate to allow specific, intratumoral delivery of CPT. To avoid nonselective uptake of the conjugates by normal tissues following

administration, the cell-penetrating function of LMWP on the conjugates is masked by heparin binding. This system was designed such that after accumulation at the tumor via the enhanced permeability and retention (EPR) effect, protamine can be subsequently administered to unmask heparin inhibition on LMWP, permitting intracellular uptake of the LMWP-PR-CPT conjugates. Once inside the tumor, CPT molecules are detached from the PR chain by hydrolysis, yielding a sustained concentration of CPT within tumor cells. In this paper, we demonstrated the in vitro feasibility of this delivery system. The LMWP-PR-CPT conjugates yielded a sevenfold increase in the overall CPT solubility, as well as a sustained release of CPT over a period of more than 7 days. Intracellular uptake of these conjugates by A2780 human ovarian cancer cells and regulation of such uptake by heparin and protamine were tested by MTT assay and confocal/flow cytometric methods, respectively.

AB A self-assembled pseudopolyrotaxane consisting of lactoside-displaying cyclodextrin (CD) "beads" threaded onto a linear polyviologen "string" was investigated for its ability to inhibit galectin-1-mediated T-cell agglutination. The CDs of the pseudopolyrotaxane are able to spin around the axis of the polymer chain as well as to move back and forth along its backbone to alter the presentation of its ligand. This supramolecular superstructure incorporates all the advantages of polymeric structures, such as the ability to span large distances, along with a distinctively dynamic presentation of its lactoside ligands to afford a neoglycoconjugate that can adjust to the relative stereochemistries of the lectin's binding sites. The pseudopolyrotaxane exhibited a valency-corrected 10-fold enhancement over native lactose in the agglutination assay, which was greater than the enhancements observed for lactoside-bearing trivalent glycoclusters and a lactoside-bearing chitosan polymer tested using the same assay. The experimental results indicate that supramolecular architectures, such as the pseudopolyrotaxane, provide tools for investigating protein-carbohydrate interactions.

AB The binding domain of an antibody is a paradigm for the development of a synthetic host. Host-rotaxanes combine recognition elements in a similar convergent arrangement as found with antibodies. Besides forming tight complexes with various guests, host-rotaxanes are highly efficient cellular transport agents. The rotaxane operates through a passive transport mechanism, so there is no control over what cell it enters. We are currently constructing host-rotaxanes with an "on" switch to obtain cell-selectivity. Highly charged peptides will be added to the transporters, which should make them impermeable. Enzymic cleavage of these peptides will turn the transporter on and it will enter cells. The long-term goal is to create transporters that are turned on by enzymes that are over expressed at tumor sites. These transporters will become part of a new anti-cancer therapy.

AB Camptothecin (CPT) is a naturally occurring alkaloid that shows promise in antitumor activity in vitro against various tumor cell lines. Its potential clinical uses, however, are hindered by a lack of reaction selectivity and poor water solubility. Presented herein is a novel polyrotaxane (PR)-based delivery system that could potentially lead to a highly effective yet less toxic CPT therapy. The approach involves the synthesis of the PR-CPT conjugates via hydrolyzable linkages. To enhance the therapeutic efficacy of CPT, a cell-penetrating peptide, LMWP, is linked to the conjugate to allow specific, intratumoral delivery of CPT. To avoid nonselective uptake of the conjugates by normal tissues following administration, the cell-penetrating function of LMWP on the conjugates is masked by heparin binding. This system was designed such that after accumulation at the tumor via the enhanced permeability and retention (EPR) effect, protamine can be subsequently administered to unmask heparin inhibition on LMWP, permitting intracellular uptake of the LMWP-PR-CPT conjugates. Once inside the tumor, CPT molecules are detached from the PR chain by hydrolysis, yielding a sustained concentration of CPT within tumor cells. In this paper, we demonstrated the in vitro feasibility of this delivery system. The LMWP-PR-CPT conjugates yielded a sevenfold increase in the overall CPT solubility, as well as a sustained release of CPT over a period of more than 7 days. Intracellular uptake of these conjugates by A2780 human ovarian cancer cells and regulation of such uptake by heparin and protamine were tested by MTT assay and confocal/flow cytometric methods, respectively.

AB Supramol. chemical has been employed to develop flexible and adaptable multivalent neoglycoconjugates for binding galectin-1 (Gal-1). Gal-1, a dimeric lectin with two galactoside-binding sites, regulates cancer progression and immune responses. Self-assembled pseudopolyrotaxanes consisting of lactoside-displaying cyclodextrin (LCD) "beads" threaded onto polyviologen "strings" display mobile ligands as a result of cyclodextrin rotation about, and limited translation along, the polymer chain. The pseudopolyrotaxanes rapidly and efficiently precipitate Gal-1 and provide valency-corrected enhancements of up to 30-fold compared to native lactose and 20-fold over free LCD in a T-cell agglutination assay. A supramol. statistical effect was observed, wherein the efficacy of Gal-1 inhibition correlates with the number of ligands connected to each other solely through mech. and noncovalent interactions. Such flexible and adaptable self-assembled pseudopolyrotaxanes show promise for the study of multivalent interactions and targeting of therapeutically relevant lectins.

AB This review describes the development of self-assembled multivalent pseudopolyrotaxanes as flexible and dynamic neoglycoconjugates for binding Galectin-1 (Gal-1). Gal-1, a dimeric lectin with two lactoside-binding sites, plays multiple roles in a variety of cancers. Pseudopolyrotaxanes comprised of lactoside-displaying cyclodextrin (LCD) "beads" threaded onto polyviologen "strings" display highly flexible and adaptable ligands as a result of rotation of the cyclodextrin torus about, and limited translation along, the polymer chain. The pseudopolyrotaxanes rapidly and efficiently precipitate Gal-1 and provide valency-corrected enhancements of up to 30-fold over native lactose and 20-fold over free LCD in a T-cell agglutination assay. These results show that the flexible and dynamic ligand presentation afforded by supramol. assemblies, such as the pseudopolyrotaxanes, is a useful strategy for the study of protein-carbohydrate interactions and the exploitation of multivalency for targeting therapeutically relevant lectins.

AB In the development of anti-cancer drugs, it is important to yield selective cytotoxicity primarily against tumor tissues. To achieve this goal, the use of a polymer-drug conjugate appears to be appealing, simply because it can take the advantage of the so-called enhanced permeability and retention (EPR) effect due to vascular leak in tumors. Among various types of polymers, polyrotaxane (PR) is an interesting candidate and warrants further consideration. It is a self-assembled polymer made entirely of biocompatible components, by threading α-cyclodextrin (α-CD) mols. with the poly(ethylene glycol) (PEG) chain. The abundance in functional -OH groups on the CD residues renders PR the capability of carrying a large dose of small anti-tumor agents for delivery. Herein, we presented a novel PR-based delivery system using doxorubicin (DOX) as the model anti-cancer drug. Daunorubicin (DNR) was conjugated to the PR polymer via hydrolysable linkages, and upon hydrolysis, doxorubicin was released as the cytotoxic drug. To facilitate an intracellular uptake by the tumor cells of the PR-DOX conjugates, a cell-penetrating low mol. weight protamine (LMWP) peptide was further attached to the two termini of the PR chain. Using an innovative principle established in our laboratory, such as via the inhibition of the cell-penetrating activity by binding with heparin and reversal of this inhibition by subsequent addition of protamine, cellular uptake of the polymer-drug conjugates could be readily regulated. In this paper, we performed in vitro studies to demonstrate the feasibility of this delivery system. The LMWP-PR-DOX conjugates, which yielded a sustained release of DOX over a period of greater than 4 days, were successfully synthesized. Intracellular uptake of these conjugates by A2780 human ovarian cancer cells and regulation of such uptake by heparin and protamine were confirmed by using the MTT assay and

also the confocal microscopy method.

AB The present invention provides for methods and compns. for transporting agents and macromols. across biol. membranes. In one embodiment, the invention relates to a method for enhancing transport of a selected agent across a biol. membrane, wherein a biol. membrane is contacted with a composition containing a biol. active rotaxane capable of selectively transporting the selected agent. The host-rotaxane is effective to impart to the agent an amount of transport and/or rate of trans-membrane transport across a biol. membrane that is greater than the amount and/or rate of trans-membrane transport of the agent without the host-rotaxane.

AB A self-assembled pseudopolyrotaxane consisting of lactoside-displaying cyclodextrin (CD) "beads" threaded onto a linear polyviologen "string" was investigated for its ability to inhibit galectin-1-mediated T-cell agglutination. The CDs of the pseudopolyrotaxane are able to spin around the axis of the polymer chain as well as to move back and forth along its backbone to alter the presentation of its ligand. This supramolecular superstructure incorporates all the advantages of polymeric structures, such as the ability to span large distances, along with a distinctively dynamic presentation of its lactoside ligands to afford a neoglycoconjugate that can adjust to the relative stereochemistries of the lectin's binding sites. The pseudopolyrotaxane exhibited a valency-corrected 10-fold enhancement over native lactose in the agglutination assay, which was greater than the enhancements observed for lactoside-bearing trivalent glycoclusters and a lactoside-bearing chitosan polymer tested using the same assay. The experimental results indicate that supramolecular architectures, such as the pseudopolyrotaxane, provide tools for investigating protein-carbohydrate interactions.

AB Polyrotaxanes which comprise 2-50 cyclic oligosaccharides threaded onto a

linear polyoxyalkylene terminated with substituents ≥0.6 nm in diameter, with metal complexes or triiodobenzoyl moieties as substituents on the cyclic oligosaccharides, are useful as contrast agents for MR tomog. and x-ray diagnosis. These compds., with a mol. weight of 104-2 + 105, accumulate in regions of elevated vascular permeability (e.g. tumors), give information on perfusion of tissues and on blood volume, and are useful in angiog., lymphog., and diagnosis of inflammation. These polyrotaxanes, when used in MR imaging and diagnosis, can be 10-20% saturated with paramagnetic cations, compared to 5% for dextran chelate derivs. used previously. They can be administered parenterally in doses <1 mg/kg as solns. isoosmolar to blood, are relatively nontoxic, and are completely eliminated from the body. They are prepared by reaction of cyclic oligosaccharides with H-terminated polyoxyalkylenes in a polar solvent, followed by functionalized terminating groups.

AB Two 9-dihydrotaxane analogs were synthesized and tested for in vitro potency and in vivo efficacy against murine and human tumor xenografts in mice. The in vitro potency of 9-dihydrotaxol (9-DH-t) and 10-deacetyl-9-dihydrotaxol (10-DeAc-9-DH-t) was generally less than that of paclitaxel against human and murine tumor cells. However, both analogs were at least 20-fold more soluble than paclitaxel in water. The analogs yielded cure rates ≥ 60% against human MX-1 solid tumor xenografts in mice, compared with a cure rate of 10% for mice treated with paclitaxel. Both of the analogs were more effective than paclitaxel for treatment of murine M109 solid tumor in mice. 10-DeAc-9-DH-t was as effective as paclitaxel against murine B16 ascites tumor, while 9-DH-t was less effective. Both 10-DeAc-9-DH-t and 9-DH-t were demonstrably less toxic than paclitaxel. At equal dosages 9-DH-t produced serum concns. greater than paclitaxel, while 10-DeAc-9-DH-t yielded serum concns. less than paclitaxel. However, the decrease in toxicity of 9-DH-t and 10-DeAc-9-DH-t allowed a 4-fold increase in daily dosage. These two 9-dihydrotaxane analogs yielded favorable preclin. data and demonstrated good potential for further development.

I

AB A novel reduced taxane, 13-acetyl-9(R)-dihydrobaccatin III has been isolated from Taxus canadensis. The selective C-13 deacetylation of this isolate has allowed for the preparation of a wide variety of 9(R)-dihydrotaxane analogs, e.g. I. In general, this series has shown greater stability and water solubility than the 9-carbonyl series while retaining antimicrotubule and tumor cell cytotoxicity activities relative to taxol. Placement of polar functionalities at the C-7 position results in loss of activity whereas alkylation or acylation of either C-7 or C-9 hydroxyl groups ameliorate the activity.

AB Review with 19 refs. The 9(R)-dihydrotaxanes are a new family of semisynthetic antitumor agents which show great promise as a second generation class of antimicrotubule agents. These compds. have increased water solubility and stability as compared to taxol and also exhibit excellent activity in tumor models. Other advantages of the 9(R)-hydroxyl group can be found in its use as an addnl. site for chemical modification towards the preparation of new derivs. Furthermore, its effect on the surrounding functionalities allows for access to novel chemical and ring systems from this taxane template.

* STRUCTURE DIAGRAM TOO LARGE FOR DISPLAY - AVAILABLE VIA OFFLINE PRINT *

AB Reaction of the C-7 hydroxyl group on the 9-dihydrotaxane skeleton, e.g. I, with triflic anhydride causes a major skeletal rearrangement to occur leading to contraction of ring B. A side product, II, is the formation of a ring C-fused cyclopropane structure. The requisite C-13 phenylisoserinate side chains are appended via an initial deacylation of the C-13 acetate followed by reacylation and deprotection. These rearranged compds., e.g. III (R = Bz, CO2CMe3) and IV show very similar structural features with the parent 9-dihydrotaxane skeleton and also retain biol. activity.

AB   This review focuses on the supramol. challenge of enhancing multivalent
     binding between ligands and proteins or biol. receptors on cell
     surfaces.  The authors' special interest is using supramol.-structured
     polymers, namely, polyrotaxanes consisting of ligand-immobilized
     α-cyclodextrins (α-CDs) threaded onto a poly(ethylene glycol)
     (PEG) chain capped at both terminals with bulky end groups via
     biodegradable linkages.  The structural characteristics of these
     polyrotaxanes involve sliding and rotational motion of the ligands
     immobilized on α-CDs along a PEG chain, thus facilitating access to
     binding sites on proteins.  This approach provides a novel biomaterial
     design in the field of drug delivery and tissue engineering.

AB A functioning nanomachine in the form of a supramol. nanovalve that opens and closes the orifices to mol.-sized pores and releases a small number of mols. on demand is reported. The nanovalve, which is used to open and close the nanocontainer, is a pseudorotaxane composed of two components-a long thread containing a 1,5-dioxnaphthalene donor unit, which is attached to the solid support, and the moving part, the tetracationic cyclophane acceptor/receptor, cyclobis(paraquat-p-phenylene), which controls access to the interior of the nanopore. The nanocontainer is made out of mesoporous silica by using a dip-coating method. Operating the nanovalve involves three steps: (i) filling the container, (ii) closing the valve, and (iii) opening the valve to release the contents of the container on demand. The tubular pores, which are approx. 2 nm wide, are filled with stable luminescent Ir(ppy)3 mols. by allowing them to diffuse into the open pores. The orifices are then closed by pseudorotaxane formation. An external reducing reagent (NaCNBH3) is used to effect dethreading of the pseudorotaxane so as to unlock the tubes and allow the guest mols. to be released. This nanovalve is a supramol. machine consisting of a solid framework with moving parts capable of doing useful work.

AB The invention relates to a multivalently interactive mol. assembly which can effectively and stably bind to a target substance in vivo or in vitro, a capturing agent comprising said multivalently interactive mol. assembly for capturing an object of interest in vivo or in vitro, a drug carrier which aids administration of a drug, a calcium chelating agent which can effectively chelate calcium, and a drug enhancer which can be administered with a drug to assist in e.g. absorption of the drug. The invention discloses a multivalently interactive mol. assembly having a plurality of functional groups or ligands, in which a ratio between Rh and Rg expressed as Rh/Rg is 1.0 or less. Here, Rh is a hydrodynamic radius calculated from a dynamic light scattering assay performed in aqueous solution, and Rg is a radius of gyration determined based on the Zimm plot generated using data obtained by a static light scattering assay. Specifically, the invention discloses polyrotaxanes, the synthesis of which is described.

AB A review. The challenge to multivalent binding between ligands and proteins or biol. receptors on cell surfaces has been focused on using supramol.-structured polymers, polyrotaxanes. Our designed polyrotaxanes consist of ligand-immobilized α-cyclodextrins (α-CDs) threaded onto a linear polymeric chain (polyethylene glycol) (PEG) capped both terminals with bulky end-groups via biodegradable linkages. Structural characteristics of these polyrotaxanes involve sliding and rotational motion of the ligands immobilized on α-CDs along a PEG chain as to easily face to binding sites on proteins, which can contribute much to enhanced multivalent binding with proteins.

LANGUAGE: English
AB Kinetic anal. of interactions between biotin-polyrotaxane or biotin-α-cyclodextrin (biotin-α-CD) conjugates and streptavidin was carried out as a model of new targeting to transporters using the surface plasmon resonance (SPR) technique. The biotin-polyrotaxane conjugates, in which biotin-introduced α-CDs are threaded onto a poly(ethylene oxide) chain capped with bulky end-groups, are expected to increase the valency of biotin from monovalent to multivalent binding. The number of biotins conjugated with one polyrotaxane mol. varied from 11 to 78, and apparently increased the association equilibrium constant (Ka), assuming pseudo-first-order kinetics. A detailed dissociation kinetics was analyzed and the re-binding of the biotin-polyrotaxane conjugates was observed on the streptavidin-deposited SPR surface. The magnitude of the re-binding is likely to become larger with increasing the number of biotins, suggesting multivalent interaction on the SPR surface. To quantify the effect of valency, competitive inhibition assay was performed in terms of the supramol. structure of the polyrotaxane. The inhibitory potency of the biotin-polyrotaxane conjugate was found to be 4-5 times greater than that of the biotin-α-CD conjugate. Therefore, the biotin-polyrotaxane conjugates by supramol. formation of the biotin-α-CD conjugate significantly switches from monovalent to multivalent bindings to the model binding protein, streptavidin.

AB Circular triplex-forming oligonucleotides (CTFOs) have previously been shown to bind tightly to short single-stranded homopurine DNAs in a sequence-specific manner. In view of the importance of double-stranded DNA as a target in the development of gene-specific therapeutic and diagnostic agents, we have investigated the binding of CTFOs to double-helical DNA. DNA-binding expts. show that a CTFO can recognize its homopurine target when the target is embedded in a long duplex. Unlike their linear counterparts, CTFOs bind the double helix in two topol. distinct forms. The more stable of the two complexes is found to be a pseudorotaxane, having the same topol. as the sliding clamp protein subunits associated with some DNA and RNA polymerases. Circular triplex-forming oligonucleotides have been shown to bind the DNA double helix in a topol. manner which is unprecedented among synthetic ligands. This novel binding motif allows a synthetic CTFO to be irreversibly locked onto a circular double-stranded DNA target without covalently modifying the target.

AB Honolulu, Hawaii - Once every 5 years, chemists from North America, Japan, New Zealand, and Australia come together for the International Chemical Congress of Pacific Basin Societies. At last month's meeting, over 10,000 researchers discussed topics that included a new molecular electronic switch and new hope for fighting diabetes and Alzheimer's disease.
